

# CONNECTORS

Remember that connectors are words or groups of words that are used in a text to relate ideas. They can be different kinds, ACCORDING TO the type of connection they make.

Look for 6 CONNECTORS in the following text and say what kind of connector each one is:

Ants are social insects, **therefore**, they form colonies that range from a few dozens of individuals to very organized colonies that can occupy large territories and have millions of individuals.

Ants have been established in almost every kind of land, the fact that they inhabit so many places is due to their social organization, also due to their ability to modify their environment, adapt, and defend themselves.

In order to have the great order they have inside the anthill, they need a sophisticated communication system.

One of the measures they have to communicate is through substances that they secrete, so that they all follow the trail to get to the food or also to find their way back home, that's why, when we pass our finger through a row of ants, yes, without harming them, we break that line so the ants are looking for the path again.

When the danger is inside the colony, they strike with their tails in order to send alert vibrations. Likewise, some ants squeal or buzz by rubbing parts of their body which indicates a danger warning or a request for help.

Another way they have to communicate is by rubbing their antennae. With the antenna, the ants smell. Obviously, according to what they feel, they know if they need to convey a danger signal, such as if there is any prey that can attack or if they are from the same colony.
